10 **Abstract**

11 Soft-tissue calcification is characterised by the deposit of calcium in the damaged  
12 collagen fibres. The pathology of the phenomenon is not fully known. Trauma, spinal  
13 cord injury and traumatic brain injury have been reported as possible risk factors.  
14 Hypertrophic calcification of medial collateral ligament can be post-traumatic with  
15 unexplained aetiology. It can restrict the normal range of joint motion, affecting  
16 performance of activities of daily living, resulting in disturbance of quality of life. It  
17 may be managed conservatively, but if unsuccessful, surgical removal of the  
18 calcification may be carried out. Here, we present a case of post-traumatic  
19 heterotrophic calcification of medial collateral ligament of knee joint and review of  
20 current literature.

21 **Keywords:** Heterotrophic calcification, Lower extremity functional scale, medial  
22 collateral ligament, Physiotherapy.

23  
24 **Introduction**

25 Soft-tissue calcification results due to heavy deposits of calcium within or between  
26 the collagen fibres. The most common site of calcification is upper quadrant,

27 particularly involving rotator cuff tendon, which is seen in one out of every five  
28 healthy individuals. The causes include humoral factors, local factors, including  
29 hypercalcaemia and hypoxia, neural factors, variation in sympathetic nervous  
30 activity, prolonged period of immobilisation and mobilisation with frequent exercise  
31 bouts after long-term immobilisation. These causes are not only responsible for the  
32 development of Pellegrini-Stieda Syndrome (PSS) but also trigger neurogenic ectopic  
33 bone formation and calcification. PSS usually presents with history of trauma and  
34 recurrent micro traumas.<sup>(1)</sup> Calcification of the femoral origin of the medial collateral  
35 ligament (MCL) of the knee is called Pellegrini–Stieda lesion. Post-traumatic  
36 ossification of the whole MCL rarely occurs and results in limitation of range of  
37 motion of the knee.<sup>(2)</sup> PSS should not only be considered during differential diagnosis  
38 of knee pain, swelling and limitation of range of motion, but also screened during  
39 assessment of patient for neurologic rehabilitation after traumatic brain injury.<sup>(3)</sup>  
40 Patients with history of traumatic brain injury, spinal cord injury and other upper  
41 motor neuron lesions can present with neurogenic heterotrophic ossification at major  
42 synovial joint which are surrounded by spastic muscle. Heterotrophic ossification  
43 (HO) can lead to the development of nerve impairment, joint ankyloses, osteoporosis  
44 and complex regional pain syndrome. The resultant decrease in ROM affects the  
45 patient's activities of daily living ultimately producing decline in quality of life.<sup>(4)</sup>  
46 Management of HO focuses on arresting its progress and minimising the effects of  
47 limitation on the functions of the joint. Non-surgical management is advisable for  
48 early HO; however, joint ankyloses and significant limitation of ROM needs surgical  
49 excision.<sup>(5)</sup> Previously, radiological and clinical presentation of true heterotopic bone  
50 in patients with paralysis has been confused with trauma, neoplasm, osteomyelitis  
51 and thrombophlebitis.<sup>(6)</sup> Heterotrophic calcification is an uncommon case  
52 encountered in orthopaedic departments.<sup>(7)</sup> Total knee arthroplasty may result in  
53 ankylosis due to calcification of collateral ligaments and intra articular bone

54 formation.<sup>(8)</sup> The Lower Limb Function Scale LEFS is preferred against SF-36  
55 questionnaire for the documentation of physical functions in patients with lower  
56 extremity dysfunctions in terms of clinical efficiency and sensitivity.<sup>(9)</sup>

57

### 58 **Case Report**

59 A 14-year-old boy had a road accident while driving a motorbike, injuring his left  
60 lower extremity. He was taken to the trauma centre of a public hospital. Emergency  
61 medical care was provided that included stitching of the wound and a back slab, after  
62 which the patient was discharged. After a couple of days, in the last week of May  
63 2019, an orthopaedic surgeon was consulted for further treatment at Amin Welfare &  
64 Teaching Hospital, Sialkot. Detailed examination and necessary investigations were  
65 carried out. There was massive swelling around the knee joint. As the swelling  
66 settled, plaster was applied for eight weeks. Valgus stress test was positive.  
67 Radiographic examination of the knee joint revealed an abnormal bone-like structure  
68 on the medial aspect of the knee connecting both the femoral and tibial medial  
69 condyles (Figure 1). An MRI scan without contrast was performed to confirm the  
70 diagnosis, which revealed heterotrophic calcification in the lower part of the medial  
71 collateral ligament at the tibial attachment site along with moderate partial thickness  
72 tear of the medial collateral ligament. There was limited range of motion of the  
73 affected knee along with pain and difficulty in bearing weight on the left limb. He  
74 was referred to the physiotherapy department. Consent form was signed by the father  
75 of the boy. Detailed examination was carried out by a competent physical therapist.  
76 There was only 5° active flexion and 10° passive flexion on the knee joint. There was  
77 a hard bony end feel at the limit of passive flexion range of motion (ROM). This  
78 limitation was affecting all his activities of daily living (ADL). His Lower Extremity  
79 Function Scale (LEFS) score was 10/80 at the baseline.

80 His treatment plan was designed to regain Flexion ROM of the knee, relief pain,  
81 subside swelling and restore ADLs, ultimately improving his quality of life (QOL).  
82 The treatment included TENS, ultrasonic therapy, wax therapy, relaxation massage,  
83 passive mobilisation techniques including Kaltenborn Grade-III posterior glide to  
84 medial aspect of upper end of tibia in accordance with concave rule, and patellar  
85 caudal and lateral glides, Hold Relax (PNF) technique, stretching of tight  
86 (quadriceps) muscles, strengthening exercises of the weak (Hamstrings) muscles.  
87 Partial weight bearing using crutches was incorporated to improve the gait.  
88 Physiotherapy was administered thrice a week for six weeks. After six weeks, knee  
89 flexion was 120° and knee extension from flexed position was 0°, end feel was firm  
90 and ADLs could be performed with relative ease. There was appreciable  
91 improvement in the LEFS score (57/80). A comprehensive home programme was  
92 prescribed and follow up comprising re-assessment and treatment including manual  
93 mobilisation techniques, stretching of tightened muscles and strengthening exercises  
94 of the weak muscles was carried out for six weeks.

95

## 96 **Discussion**

97 Our study supports the findings of Gocken N et al who proposed that heavy exercise  
98 immediately after long period of immobilisation augments PSS.<sup>(1)</sup> Mendes LF et al  
99 proved that ossification in PS disease is not confined to MCL but may also involve  
100 the adductor magnus tendon.<sup>(10)</sup> Bossche LV, Vanderstraeten G reviewed if radiation  
101 therapy was useful in prevention and treatment of heterotopic ossification.<sup>(11)</sup> This  
102 study is in contradiction with the treatment of ossified MCL reported by Mohamed  
103 AR et al<sup>(2)</sup> Our study supports the results of another case report by Muschol M, et al  
104 who reported that pathologic calcifications not only involves rotator cuff tendon but  
105 also affects other structures of the locomotor system. Initially they treated all patients  
106 conservatively by needling and local anaesthetic. Surgical removal of the deposit was

107 considered only after poor results of conservative treatment. Pain immediately  
108 subsided after open resection.<sup>(12)</sup>

109

### 110 **Conclusion**

111 Any trauma followed by knee immobilisation can result in Heterotrophic  
112 calcification of medial collateral ligament of knee. If diagnosed early, it can be  
113 managed with physical therapy.
